M. Hohle:

Physics 77: Introduction to Computational Techniques in Physics
syllabus:

```
String   = 'Hello ' + ''World''
List     = [1, 2, 3, 5, ''World'' ]
Tuble    = (1, 2)
Dict     = {'A': 1, 'B': 2}
Array    = np.array([1, 2, 3, 5])
pd.DataFrame
```

L = [1, 2, 3, -2]   **list: default format in Python**

type: 2*L

Out[1]: [1, 2, 3, -2, 1, 2, 3, -2]

This is the first thing we need to do: loading packages/libraries/modules

import numpy as np

alias **you** set

name of library/module

We will use some **standard libraries** such as

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
```

etc…

type:

np.   and use the auto complete (tab)

```
String   = 'Hello ' + ''World''
List     = [1, 2, 3, 5, ''World'' ]
Tuble    = (1, 2)
Dict     = {'A': 1, 'B': 2}
Array    = np.array([1, 2, 3, 5])
pd.DataFrame
```

```
In [32]: np.
```

ALLOW_THREADS
AxisError
BUFSIZE
CLIP
ComplexWarning
DataSource
ERR_CALL
ERR_DEFAULT

try the following commands:

```
dir(L)
dir(L_arr)

L.shape()
L_arr.shape()
```

L_arr = np.array(L)

Name	Type	Size	Value
L	list	4	[1, 2, 3, -2]
L_arr	Array of int32	(4,)	Min: -2 Max: 3

try now something like:

```
String    = 'Hello ' + ''World''
List      = [1, 2, 3, 5, ''World'' ]
Tuble     = (1, 2)
Dict      = {'A': 1, 'B': 2}
Array     = np.array([1, 2, 3, 5])
pd.DataFrame
```

```
a = 2
b = 3
```

Try to type and run the following numerical operations:

1) a*b
2) a = b
3) c = a – b
4) ab**
5) np.exp(a)
6) np.power(c,3)
7) np.log(a)

```
np.log10(10)
np.log2(2)
```

recall: logB(x) = logA(x)/logA(B)

Now with vectors. Type:

```
v1 = np.array([1,5,0,-3])
v2 = np.array([3,-1,2,2])
```

```
String   = 'Hello ' + ''World''
List     = [1, 2, 3, 5, ''World'' ]
Tuble    = (1, 2)
Dict     = {'A': 1, 'B': 2}
Array    = np.array([1, 2, 3, 5])
pd.DataFrame
```

Try to type and run the following numerical operations:

```
1) v1 + v2
2) v1 + 2
3) v1*2          compared to L*2 !
4) v1*v2
5) np.dot(v1,v2)
6) np.outer(v1,v2)
```

Now with vectors. Type:

```
v1 = np.array([1,5,0,-3])
v2 = np.array([3,-1,2,2])
```

1) np.dot(v1,v2)
2) np.outer(v1,v2)

3) np.multiply()

```
String   = 'Hello ' + ''World''
List     = [1, 2, 3, 5, ''World'' ]
Tuble    = (1, 2)
Dict     = {'A': 1, 'B': 2}
Array    = np.array([1, 2, 3, 5])
pd.DataFrame
```

$$(a \quad b \quad c) \begin{pmatrix} \alpha \\ \beta \\ \gamma \end{pmatrix} = a\alpha + b\beta + c\gamma$$

$$\begin{pmatrix} \alpha \\ \beta \\ \gamma \end{pmatrix} (a \quad b \quad c) = \begin{pmatrix} a\alpha & \alpha b & \alpha c \\ a\beta & \beta b & \beta c \\ a\gamma & \gamma b & \gamma c \end{pmatrix}$$

```
np.outer(v1,v2)

Out[11]:

array([[ 3, -1,  2,  2],
       [15, -5, 10, 10],
       [ 0,  0,  0,  0],
       [-9,  3, -6, -6]])
```

```
np.dot(v1,v2)

Out[10]:     -8
```

creating matrix from vectors:

```
v_tot_row        = np.array([v1,v2])
v_tot_col        = np.column_stack([v1,v2])
```

creating matrix from random numbers and zeros:

```
M                = np.random.uniform(0,1,(5,6,7))
Z                = np.zeros((5,6,7))
```

common matrix operations:

```
v_tot_col_trans = v_tot_col.transpose()
```

np.max(v_tot_row)   **check also:** np.argmax(v_tot_row)

np.min(v_tot_row)

np.mean(v_tot_row)

np.var(v_tot_row)

np.std(v_tot_row)

```
String    = 'Hello ' + ''World''
List      = [1, 2, 3, 5, ''World'' ]
Tuble     = (1, 2)
Dict      = {'A': 1, 'B': 2}
Array     = np.array([1, 2, 3, 5])
pd.DataFrame
```

```

loops: Python syntax

```python
L  = list(np.arange(0,100,1))
L2 = L

for i, l in enumerate(L):
    L2[i] = l**2
```

actual **pythonian** way:

```python
L3 = [l**2 for l in L]
```

```
for
if
else
while
...
```

called **comprehension**
→ more compact
→ faster!

actual loop

statement

loops: Python syntax

```python
L  = list(np.arange(0,10000,1))

t1 = datetime.now()

for i in range(10000):
    L2 = L

    for i, l in enumerate(L):
        L2[i] = l**2

t2 = datetime.now()
dt = (t2 - t1)/10000
print("Average Runtime: " + str(dt))
```

1.339 ms

```python
from datetime import datetime
```

loops: Python syntax

```python
L  = list(np.arange(0,10000,1))

t1 = datetime.now()

for i in range(10000):

t2 = datetime.now()
dt = (t2 - t1)/10000
print("Average Runtime: " + str(dt))
```

1.339 ms

loops: Python syntax

```python
L  = list(np.arange(0,10000,1))
```
1.339 ms

```python
t1 = datetime.now()

for i in range(10000):
    L2 = [l**2 for l in L]
```
0.486 ms

```python
t2 = datetime.now()
dt = (t2 - t1)/10000
print("Average Runtime: " + str(dt))
```

loops: Python syntax

```python
L  = list(np.arange(0,10000,1))
```

1.339 ms

0.486 ms

```python
t1 = datetime.now()

for i in range(10000):

t2 = datetime.now()
dt = (t2 - t1)/10000
print("Average Runtime: " + str(dt))
```

loops: Python syntax

```
L  = list(np.arange(0,10000,1))
```
1.339 ms

0.486 ms

```
t1 = datetime.now()

for i in range(10000):
    L = []
    N = 10000

    for n in range(N):
        L += [n**2]
```

4.1 ms

```
t2 = datetime.now()
dt = (t2 - t1)/10000
print("Average Runtime: " + str(dt))
```

Always use comprehension!

functions

lambda	→ anonymous function
map	→ function/method
def	→ function/method

functions

lambda	**→ anonymous function**

lets write a function that tells us how far we can jump
from a height h_0

lambda   → anonymous function
map   → function/method
def   → **function/method**

input: v_0 $[m/s]$
           h_0 $[m]$

g = 9.81 m/s as default

h_0

$$y(x) = -\frac{g}{2}\frac{x^2}{(v_0\cos\alpha)^2} + x\,tan\alpha + h_0$$

$$\bar{x} = \frac{v_0\cos\alpha}{g}\left(v_0\sin\alpha + \sqrt{(v_0\sin\alpha)^2 + 2gh_0}\right)$$

$\bar{x}$

lets write a function that tells us how far we can jump
from a height h_0

```python
import numpy as np
import matplotlib.pyplot as plt

def Jump(v_0, h_0, g = 9.81, alpha = 0):

    alpha  = alpha * np.pi/ 180 #degrees to rad

    vsin    = v_0 * np.sin(alpha)
    vcos    = v_0 * np.cos(alpha)

    x_bar   = (vcos/g) * (vsin + np.sqrt(vsin**2 + 2*g*h_0))

    print(f'Distance is: {x_bar:.3f}m')
```

```
In [16]: Jump(10, 20)
Distance is: 20.193m

In [17]: Jump(10, 20, alpha=45)
Distance is: 20.258m

In [18]: Jump(10, 0, alpha=45)
Distance is: 10.194m
```

lets write a function that tells us how far we can jump
from a height h_0

```python
def Jump(v_0, h_0, g = 9.81, alpha = 0):
...

    x_bar  = (vcos/g) * (vsin + np.sqrt(vsin**2 + 2*g*h_0))
    x_plot = np.arange(0, x_bar, x_bar/100)

    y      = (-0.5 * g *x_plot**2)/ ((v_0*np.cos(alpha))**2)\
                + np.tan(alpha) * x_plot + h_0

    plt.plot(x_plot, y, '--', color = 'k',\
                    label = r'$v_{0}$ = ' + str(v_0) + 'm/s')
    plt.xlabel('distance [m]')
    plt.ylabel('height [m]')
    plt.legend()
    plt.show()

    print(f'Distance is: {x_bar:.3f}m')
```
lets write a function that tells us how far we can jump
from a height h_0

lambda → anonymous function
map → function/method
def → **function/method**

Jump(10, 20)

Jump(10, 20, alpha = 45)

Jump(10, 0, alpha = 45)

lets write a function that tells us how far we can jump from a height h_0

lambda → anonymous function
map → function/method
def → **function/method**

```python
def Jump(v_0, h_0, g = 9.81, alpha = 0):
...

    plt.plot(x_plot, y, '--', color = 'k',\

def   → **function/method**

```
In [11]: fun3(
         fun3(a, b=1, *c)

         No documentation available
```

c has been converted into a tuple!

```
In [29]: fun3(1,2,3)
<class 'tuple'>
1
Out[29]: 3
```

```
In [33]: fun3(2,1,1,2,3,4)
<class 'tuple'>
2
4
8
16
Out[33]: 3
```

<u>functions</u>

<u>4) optional keyword arguments of any number **kwargs</u>

lambda   → anonymous function
map   → function/method
def   → **function/method**

```
def fun4(a, b = 1, *c, **d):

    res = a + b

    if c:
        res = res * c

    if 'hi' in d:#dict
        print(d['hi'])

    return(res)
```

In [13]: fun4(

fun4(a, b=1, *c, **d)

No documentation available

```
fun4(2)
fun4(2, 3)
fun4(2, 3, d = 'hi')
fun4(1, hi = 'hi')
fun4(1, 3, hi = 'abc')
fun4(1, 3, 3, hi = 'abc')
```

Interpret the results!

Write a function `Jump3`, that creates a plot, only
if an optional keyword argument `plot = 'yes'`
is given.

|	
lambda	→ anonymous function
map	→ function/method
def	→ **function/method**

Put all three functions into a module, called `Jump`

```
from Jump import *

X = Jump3([10, 20, 30], [20, 20, 40], plot = 'yes')
```

<u>functions</u>   and **classes**

lambda	→ anonymous function
map	→ function/method
def	→ **function/method**

```python
class C1():

    def f1(a,b):

functions   and **classes**

lambda   → anonymous function
map   → function/method
def   → **function/method**

so far, we inherited methods from a super (aka *parent*) class to a subclass (aka *child*) via

```python
class C1():

    def f1(a,b):
        print(a+b)

class C2(C1):

    def f2(a,b):
        print(a*b)
```

What if we want **f1** *directly* in **f2**

→ for example, because **f2** is an updated version of **f1** and we don't want to copy/paste code

```
C2.
  f1
  f2
  mro
```

<u>functions</u>   and **classes**

self

lambda → anonymous function
map → function/method
def → **function/method**

```
class C1():

    def f1(a,b):
        print(a+b)

class C2():

    def f2(self, a, b):
        print(a+b)
```

    C2.f2(1,2)

TypeError: C2.f2() missing 1 required positional argument: 'b'
```

```
In [85]: InstC2 = C2()

In [86]: InstC2.f2(1,2)
2
```

functions   and **classes**

lambda   → anonymous function
map   → function/method
def   → **function/method**

```python
import numpy as np

class Encoder():

    def __init__(self):

                NT      = ['A', 'C', 'G', 'T']
                Code    = np.eye(4)

                Dict    = {key: value for key, value in zip(NT, Code)}

        self.Enc = lambda Sequence: [Dict[s] for s in Sequence]

        #return(self.Enc)

    def Encode(self, Sequence):

        print(self.Enc(Sequence))
```

the **dunder method** `__init__`

we want to establish the encoder when we initialize our class

calling the encoder for any instance (see parallel programming)

<u>functions</u>   and **classes**

```python
import numpy as np

class Encoder():

    def __init__(self):

        NT      = ['A', 'C', 'G', 'T']
        Code    = np.eye(4)

        Dict    = {key: value for key, value in zip(NT, Code)}

        self.Enc = lambda Sequence: [Dict[s] for s in Sequence]

        #return(self.Enc)

    def Encode(self, Sequence):

        print(self.Enc(Sequence))
```

<u>functions</u> and **classes**

lambda → anonymous function
map → function/method
def → **function/method**

```python
import numpy as np

class Encoder():

    def __init__(self):

        NT      = ['A', 'C', 'G', 'T']
        Code    = np.eye(4)

        Dict    = {key: value for key, value in zip(NT, Code)}

        self.Enc = lambda Sequence: [Dict[s] for s in Sequence]
        #return(self.Enc)

    def Encode(self, Sequence):

        print(self.Enc(Sequence))
```
```
In [92]: MyEncoder = Encoder()

In [93]: MyEncoder.Encode('ACCTTGGTA')
[[1, 0, 0, 0], [0, 1, 0, 0], [0, 1, 0, 0], [0, 0, 0, 1],
[0, 0, 0, 1], [0, 0, 1, 0], [0, 0, 1, 0], [0, 0, 0, 1], [1,
0, 0, 0]]
```

Encoder
  └ m __init__
  └ m Encode

functions   and **classes** & the super() method

```
lambda          → anonymous function
map             → function/method
def             → function/method
```

```python
class C1():

    def f1(self, a, b):
        res = a + b

    return res

class C2(C1):

    def f2(self, a, b, c, d):
        res = super().f1(a,b)

    print(c*d + res)
```

What if we want **f1** *directly* in **f2**

→ for example, because f2 is an updated version of f1 and we don't want to copy/paste code

we actually would need *self* here too, but it is included in super per default

functions   and **classes** & the super() method

lambda   → anonymous function
map   → function/method
def   → **function/method**

```python
class C1():

        def f1(self, a, b):
                res = a + b

                return res

class C2(C1):

        def f2(self, a, b, c, d):
                res = super().f1(a,b)
                print(c*d + res)
```

What if we want **f1** *directly* in **f2**

→ for example, because f2 is an updated version of f1 and we don't want to copy/paste code

1st: calling an instance of C2 (hence super is perfect for inheriting __init__

f2 is now executing **f1** too
→ code is more compact
→ less error prone

```python
In [103]: c = C2()

In [104]: c.f2(1,2,3,4)
15
```

<u>functions</u>   and **classes** & the `super()` method   lambda   → anonymous function
                                                            map   → function/method
                                                            def   → **function/method**

```
class C1():

    def f1(self,a,b):
        print(a+b)

class C2(C1):

    def f2(self,a,b):
        super().f1(a,b)
        print(a*b)

class C3(C2):

    def f3(self,a,b):
        super().f2(a,b)
        print(a**b)
```

We can now go on and inherit as we did before:

```
In [112]: c = C3()

In [113]: c.f3(2,3)
5
6
8
```

<u>functions</u>   and **classes** & the super() method

lambda → anonymous function
map → function/method
def → **function/method**

```python
class C1():

    def f(self,a,b):
        print(a+b)

class C2(C1):

    def f(self,a,b):
        super().f(a,b)
        print(a*b)

class C3(C2):

    def f(self,a,b):
        super().f(a,b)
        print(a**b)
```

In practice, the fs have usually the same name!

```
In [112]: c = C3()

In [113]: c.f3(2,3)
5
6
8
```

<u>functions</u>   and **classes** & the `super()` method

lambda   → anonymous function
map   → function/method
def   → **function/method**

```python
class C1():

    def f(self,a,b):
        print(a+b)
```

In practice, the fs have usually the same name!

```python
class C2(C1):

    def f(self,a,b):
        #super().f(a,b)
        print(a*b)
```

it did not inherit the first **f**!

```python
class C3(C2, C1):

    def f(self,a,b):
        super().f(a,b)
        print(a**b)
```

```
In [124]: c = C3()

In [125]: c.f(2,3)
6
8
```

<u>functions</u>   and **classes** & the `super()` method

```python
class C1():

    def f(self,a,b):
        print(a+b)

class C2():

    def f(self,a,b):
        #super().f(a,b)
        print(a*b)

class C3(C1, C2):

    def f(self,a,b):
        super().f(a,b)
        print(a**b)
```

In practice, the fs have usually the same name!

this time it did not inherit the *second* **f**!

```
In [128]: c = C3()

In [129]: c.f(2,3)
5
8
```

functions and **classes** & the super() method

super refers to the **next class in line**!
Always check *mro* (method resolution order)
in order to see which path inheritance went!

```python
class C3(C2, C1):

    def f(self,a,b):
        super().f(a,b)
        print(a**b)
```

```
C3.mro()
[__main__.C3, __main__.C2, __main__.C1, object]
```

```python
class C3(C1, C2):

    def f(self,a,b):
        super().f(a,b)
        print(a**b)
```

```
C3.mro()
[__main__.C3, __main__.C1, __main__.C2, object]
```

lambda   → anonymous function
map   → function/method
def   → **function/method**

```python
class C1:
    def f(self, a, b):
        print(a + b)

class C2:
    def f(self, a, b):
        print(a * b)

class C3(C2, C1):

    def f(self, a, b):
        super(C2, self).f(a, b)

        super().f(a, b)

        print(a ** b)
```

```
In [112]: c = C3()

In [113]: c.f3(2,3)
5
6
8
```

Check mro!

functions   and **classes**   homework

lambda   → anonymous function
map   → function/method
def   → **function/method**

```python
import numpy as np

class Encoder():

    def __init__(self):

        NT      = ['A', 'C', 'G', 'T']
        Code    = np.eye(4)

        Dict    = {key: value for key, value in zip(NT, Code)}

        self.Enc = lambda Sequence: [Dict[s] for s in Sequence]

        return(self.Enc)

    def Encode(self, Sequence):

        print(self.Enc(Sequence))
```

functions

lambda → anonymous function
map → function/method
def → **function/method**

```python
class Map(Encoder):

    def __init__(self):
        self.Enc = super().__init__()
```

We want to inherit the *Enc* method from *Encoder*

```python
    def fun(self, s):
        NT   = ['A', 'C', 'G', 'T']
        Code = [[1,0,0,0], [0,1,0,0], [0,0,1,0], [0,0,0,1]]
        Dict = {key: value for key, value in zip(NT,Code)}

        return Dict[s]
```

That would work already!

```python
    def runboth(self, Sequence):

        print(list(map(self.Enc, Sequence))) #mapping anonymus function
        print(list(map(self.fun, Sequence))) #mapping actual function
```

functions

```python
class Map(Encoder):

    def __init__(self):
        self.Enc = super().__init__()

    def fun(self, s):
        NT   = ['A', 'C', 'G', 'T']
        Code = [[1,0,0,0], [0,1,0,0], [0,0,1,0], [0,0,0,1]]
        Dict = {key: value for key, value in zip(NT,Code)}

        return Dict[s]

    def runboth(self, Sequence):

        print(list(map(self.Enc, Sequence)))   #mapping anonymous function
        print(list(map(self.fun, Sequence)))   #mapping actual function
```
```
In [162]: M = Map()

In [163]: M.runboth('ACCTG')
[[[1, 0, 0, 0]], [[0, 1, 0, 0]], [[0, 1, 0, 0]], [[0, 0, 0, 1]], [[0, 0, 1, 0]]]
[[1, 0, 0, 0], [0, 1, 0, 0], [0, 1, 0, 0], [0, 0, 0, 1], [0, 0, 1, 0]]
```

Introduction to Unix & Python

Thank you for your attention!
